

ABSTRACT:

[0020] Components for positioning devices that can be welded together via a resistance welding process. The one component exhibits at least one circulatory embossing that protrudes beyond its surface toward the connection side and that engages in the complementary recess of the other component. The embossing can be pressed into the recess during the resistance welding process. At least one of the components exhibits on the side spaced from the circulatory embossings additional embossings that limit the impression depth of the circulatory embossing of the one component into the recess of the other component. This is done such that the surfaces facing each other of the two components maintain a fixed distance to one another.
